

Python Wordle

Kaidyn Yago: Section L

Details:

For my final project, I designed a wordle-style game in Python. Here it takes a max of 6 valid inputs as guesses for a five-letter word from a random word generator. From there the program will check each letter individually and check to see how many letters they got that match the randomly generated word. The program will then show the guess as pixel letters, green if correct, yellow if wrong placement, and grey if wrong. If all letters are green the program will stop if not the program will continue to run until either all letters are correct or all six inputs have been used. The program will then save the game as a png.

Instructions:

First off you need to install the RandomWords module

Once installed it is self-explanatory to run the program when asked for a guess input type a five letter word as your guess.

Input/Output:

My program creates a final PNG output.

Reflection:

Personally, I found this project extremely exciting as I could look forward to creativity and problem-solving in my future as a CS student. I was able to combine functions and projects from the class into a program that I had fun creating and working on. My biggest struggles were semantic errors as logic behind games can be very difficult at times. Also working with methods that were not taught in class and some advanced Python to simplify my code was a struggle as well. I entered the course with zero Python coding skills and now I believe to am pretty good at coding in Python having enjoyed the project very much. I am a computer science so things like Boolean and logic gates.
