

Custom Wordle

Kaidyn Yago

Section L

- Details of proposal
 - a. This project aims to create a simplified version of the popular Wordle game. By the end of the project, users should be able to guess a five-letter word within a limited number of attempts (e.g., six tries). The game will provide feedback on each guess, showing if letters are in the correct position, in the word but in the wrong position, or not in the word at all.
 - b. Input: User guesses in the form of five-letter words.
Output: Feedback for each guess that highlights letters in green for correct letters in the correct position, yellow for correct letters in the wrong position, and gray for incorrect letters. At the end, the game will indicate if the user guessed the word correctly or ran out of attempts.
 - c. There will be functions to check whether the letters are correctly placed and then release a color in which they are.
- Loops
 - a. A for loop will be used to track guesses to make sure there are no more than 6 guesses.
- Functions:
 - a. Function Reusability: One key function, `check_guess`, will be used multiple times in the project. This function will: Take the user's guess as input, Compare each letter with the target word, and Return feedback indicating correct letters, misplaced letters, and incorrect letters. This function will be called once per guess attempt, making it a central part of the game logic.
- Process:
 - a. Development Plan:
 - Set Up Input/Output Logic:**
Design input validation to ensure the guesses are five-letter words.
 - Create Main Game Loop:**
Implement a loop to handle guess attempts until the word is guessed or attempts are exhausted.
 - Implement Feedback Functionality:**
Develop `check_guess` to handle letter-by-letter comparison and feedback generation.
 - Testing and Debugging:**
Test the game with various words to ensure feedback accuracy and smooth gameplay.

b. Modules:

The project may use the random module to select a random target word from a predefined list.

- **Concerns:**

- a. Project Concerns and Anticipated Challenges:

- Word Validation:** Ensuring only valid five-letter words are accepted as guesses could be challenging, especially if incorporating a dictionary file for real-word validation.

- Feedback Accuracy:** Ensuring check_guess provides accurate feedback, especially distinguishing between correct positions and misplaced letters, will require careful debugging.

- Time Management:** Balancing testing and debugging within the time constraints may be challenging.

- b. Areas for TA Assistance:

- Guidance on validating words efficiently, especially if using an external word list or dictionary file.
